

PHP OOP - Constructor

[< Previous](#)[Next >](#)

PHP - The `__construct()` Function

A constructor allows you to initialize an object's properties upon creation of the object.

If you create a `__construct()` function, PHP will automatically call this function when you create an object from a class.

Notice that the construct function starts with two underscores (`__`)!

We see in the example below, that using a constructor saves us from calling the `set_name()` method which reduces the amount of code:

Example

[Get your own PHP Server](#)

```
<?php
class Fruit {
    public $name;
    public $color;

    function __construct($name) {
        $this->name = $name;
    }
    function get_name() {
        return $this->name;
    }
}

$apple = new Fruit("Apple");
echo $apple->get_name();
?>
```

[Try it Yourself »](#)

Another example:

Example

```
<?php
class Fruit {
    public $name;
    public $color;

    function __construct($name, $color) {
        $this->name = $name;
        $this->color = $color;
    }
    function get_name() {
        return $this->name;
    }
    function get_color() {
        return $this->color;
    }
}

$apple = new Fruit("Apple", "red");
echo $apple->get_name();
echo "<br>";
echo $apple->get_color();
?>
```
