

Classes and Members in Java

are classes under the same package called members in java?

No, in Java, **classes under the same package are not called members**.

- The term "**members**" in Java specifically refers to the components of a class, such as its fields (variables), methods, constructors, and nested types (like inner classes).
- Classes under the same package are simply referred to as **classes in the same package**. They share the same package namespace and can access each other's package-private (default access level) members.

For example:

Package Example

```
java

package mypackage;

class ClassA {
    int packagePrivateField = 42; // Default access level
}

public class ClassB {
    public static void main(String[] args) {
        ClassA a = new ClassA();
        System.out.println(a.packagePrivateField); // Allowed because ClassA is in the same
package
    }
}
```

Here:

- `ClassA` and `ClassB` are **classes in the same package** (`mypackage`).
- `ClassA`'s field `packagePrivateField` is accessible from `ClassB` because they are in the same package.

Summary of Key Terms:

- **Members:** Variables, methods, constructors, and nested classes inside a class.
- **Classes in the same package:** Simply classes that belong to the same namespace defined by the `package` keyword.
